

Does fiber optic communication enable short-range communication

Overview

Multi-mode fiber (MMF): Suited for shorter distances (core diameter $\approx 50\text{--}62$. Wavelength: Common transmission windows like 850 nm, 1310 nm, and 1550 nm are chosen for minimal attenuation. Fiber-optic communication is a form of optical communication for transmitting information from one place to another by sending pulses of infrared or visible light through an optical fiber. The light is a form of carrier wave that is modulated to carry information. IEEE defines short range (SR) as about 100m, and OIF defines short range as 300m. It seems that there is no clear. An SFP (Small Form-factor Pluggable) module transmits data over fiber using specific wavelengths and power levels, which directly influence how far the signal can travel before degradation occurs. This is why two modules with the same form factor can have dramatically different ranges—some limited. Fortunately, there are solutions that match any use case, from long range radio communication, to short range or in between.
