

Fiber Optic Secondary Router Bridging Settings

AI Overview

To set up a secondary router in a fiber optic network, enable bridge mode on the primary ONU or router, connect the secondary router via Ethernet, and configure it to handle DHCP and NAT. Understanding Bridge Mode Bridge mode disables the routing functions of your primary device (ONU or ISP-provided router) and allows your secondary router to manage all network tasks, including DHCP, NAT, and Wi-Fi management. This prevents double NAT, reduces latency, and ensures your secondary router can fully control the network. Steps to Configure a Secondary Router Enable Bridge Mode on the Primary Device Access the ONU or ISP router's web interface. Look for settings labeled "Bridge Mode," "IP Passthrough," or "Bridging". Some devices may require selecting a specific LAN port (e.g., LAN1) to act as the bridge. Save the settings and allow the device to reboot. Connect the Secondary Router Use an Ethernet cable to connect the WAN port of the secondary router to the designated LAN port on the primary device. If the router has self-adaptive ports, the distinction between WAN and LAN may not matter. Configure the Secondary Router Log in to the secondary router's web interface. Set the Internet access mode to Bridge (AP) or standard routing mode depending on your network design. Enter any required PPPoE credentials provided by your ISP if needed. Assign a static IP to your PC if you need to access the router's management page after bridging. Optional Wireless Settings Disable Wi-Fi on the primary device to avoid interference and duplicate SSIDs. Configure your secondary router's Wi-Fi settings for optimal coverage and security. Tips and Considerations Some ISPs restrict access to bridge mode; contact technical support if the option is unavailable. After bridging, the secondary router will handle all IP assignments, so ensure it is configured correctly...
