

# Functions of Non-PoE Switches

## Overview

A Non-PoE Switch is the most basic type of switch, primarily responsible for forwarding network data. It connects various devices (such as computers, printers, servers, etc. ) through Ethernet ports and efficiently transmits data based on MAC addresses. The core functions of a switch is a network device that operates at the Data Link Layer (Layer 2) of the OSI model, primarily used to forward data frames between devices within a Local Area Network (LAN). PoE switches address the challenge of powering connected devices, and this fundamental difference. Power over Ethernet (POE) network switch and Non-POE network switches are two fundamental components of modern network infrastructure, each with its own set of benefits and considerations. But not all devices and switches support PoE.
