

Relay protection secondary circuit maintenance

Overview

Relay maintenance generally consists of : Inspection and burnishing of contacts. Adjustments checking (iv) Breakers tripped by manual contact closing. Rare operation, critical function: Protective relays may operate only once every several. The protection circuits, CTs, VTs are also checked. Monitoring system for fast event recognizing allows operators, maintenance staff and production supervisors to prevent or fix effectively downtime issues as they happen, instead of weeks later. Long term cost reduction. Protective circuit functional testing, including lockout relay testing, must take place immediately upon installation, every 2 years thereafter, and upon any change in wiring. If applicable, documentation is required detailing how verified protection segments overlap to ensure there is not a gap. The secondary injection test method is one of the most essential techniques in electrical protection systems, particularly for verifying the accuracy, calibration, and performance of protective relays and circuit breaker trip units.
